=====

// The Strategizer Operating System Model (a new feature for release 2.0)
=====

// INTRODUCTION

// The operating system exists as a layer of software logic (and associated processes)
// that lies between software processes running in problem state (as in release 1.3)
// and the underlying hardware.

// An association is made between an operating system name (the first column in the
// CSE.ops file) and an ADN OS behavior name (the sixth column of the CSE.ops file).
// Note that the operating system names are selected from a list (based on the
// CSE.ops file) via the GUI for each computer in a Strategizer model.

// Instances of an operating system are created for each computer that runs an
// operating system with an associated ADN OS behavior name.
// The default for release 2.0 is to define the ADN behavior "ADNOSvc" for all named
// operating systems except "Generic" and "generic_operating_system".
// The operating system name is passed as a second parameter to the ADNOSvc behavior.

// A knowledgeable Strategizer user can create new operating system behaviors
// based on an understanding of the ADNOSvc behavior in this file (System.adn).
// Such user extensions must be added to the end of the System.adn file or included
// via an ADN Include statement at the end of the System.adn file.
```

FIGURE 2 PAGE - 1 -

```

// A few words about the System.adn file. This file is loaded automatically at model
// initialization prior to the processing of ADN source generated or included by the GUI.
// A search is made of the directory containing the model first, then the installation area for
// the System.adn file. The location of the System.adn file selected is logged in the trace file.
// When modifications are planned, it is recommended that a copy of the System.adn file
// be made from the installation area to the directory containing the model.

// ADN PROCESSES AND STATE

// Software processes can execute in problem state and additionally in supervisor
// state (a new feature in release 2.0).

// Processes that startup in problem state switch to supervisor state at specific points
// (OS hook locations) to execute an operating system service and then return to problem
// state.

// Processes that startup in supervisor state (the OS server processes) remain in
// supervisor state.

//-----
// OS behavior hooks are implemented as cases of an ADN switch statement.
// The logic located at each hook is described along side the corresponding
// hook constant.
//-----

Constant INITIALIZEsvc = 0; // The INITIALIZEsvc hook is executed once for each associated
                           // computer by a special initialization process.
                           // The purpose of this logic is to establish an operating system instance
                           // including its server processes and state data.
                           // Operating system data is maintained uniquely for each OS instance by using
                           // the functions osSetData and osGetData.
                           // Any user options and associated processing are included in this section.
                           // Refer to Case(INITIALIZEsvc) in the ADNnosSvc behavior and the associated
                           // server behaviors ADNnosNFS, ADNnosVolumeMgr, and ADNnosTaskMgr for additional
                           // information.

```

*// In the following hooks the active process switches from problem to supervisor state and executes the top
// level (or main operating system behavior) in a manner very similar to a behavior call. The hook identifier*

// is passed as the only parameter. In the hook descriptions that follow, example use details are provided by // the SES-supplied ADNOSSvc behavior.

```

Constant EXECUTESvc = 1; // The EXECUTESvc hook is executed at the end of the software part of
                         // Execute statement processing, just before the resulting request vector
                         // is sent to the hardware.
                         // Individual elements in the request vector are checked for remote disk IO
                         // and IO operations involving files located on volumes. Substitution or
                         // modification of the original requests are made as appropriate.
                         // Refer to Case(EXECUTESvc) in the ADNOSSvc behavior and the ADNOSNFS and
                         // ADNOSVolumeMgr behaviors for additional detail.

Constant SENDsvc = 2; // The SENDsvc hook is executed at the end of the software part
                         // of Send statement processing, just before the request is sent to the
                         // hardware. Upon exit from this section, the resulting request is sent
                         // to the hardware.
                         // Use of this hook is reserved for future development of network related
                         // OS services.

Constant SENDWAITsvc = 3; // The SENDWAITsvc hook is executed early in the processing of an incoming
                         // message sent by the Reply clause of a Receive statement.
                         // Upon exit from this section, control is passed to the Wait clause of the
                         // original Send statement for processing of the message data fields.
                         // Use of this hook is reserved for future development of network related
                         // OS services.

Constant RECEIVESvc = 4; // The RECEIVESvc hook is executed early in the processing of an incoming
                         // message from a Send statement.
                         // Upon exit from this section, control is passed to the Receive statement
                         // for processing of the message data fields.
                         // Use of this hook is reserved for future development of network related
                         // OS services.

Constant REPLYsvc = 5; // The REPLYsvc hook is executed at the end of the software part
                         // of the Reply clause (part of the Receive statement), just before the
                         // request is sent to the hardware.
                         // Use of this hook is reserved for future development of network related
                         // OS services.

Constant TASKSTARTsvc = 6; // The TASKSTARTsvc hook is executed when a Startup or Thread statement

```

FIGURE 2 PAGE - 3 -

```

// creates a new task (i.e, process or thread).
// The operating system task count is incremented. If the maximum number
// of tasks has already been reached, the creation of a new task is
// inhibited by blocking the current process (the requestor) until the task
// count drops below the maximum.
// Refer to Case(TASKSTARTsvc) in the ADNossSvc behavior and the ADNossTaskMgr
// behavior for additional details.

Constant TASKENDsvc = 7; // The TASKENDsvc hook is executed whenever a process or thread terminates.
// The operating system task count is decremented. If the task count is
// greater than the maximum, the first blocked task is allowed to continue.
// Refer to Case(TASKENDsvc) in the ADNossDsvc behavior and the ADNossTaskMgr
// behavior for additional details.

//-----// The "hr" (hardware request data) utility functions are used to access specific data necessary
// to support the current operating system functionality. In release 2.0 this is limited to requests
// generated by the Execute statement.
// The constants defined below are used in combination with the following data access utility
// functions hrGetData/hrSetData to access scalar values, and hrGetDataX/hrSetDataX to access
// vector (or subscripted) values.

// CAUTION: In considering user defined extensions to the operating system the prospective user
// should become familiar with the data currently accessible at the ADN level.
//-----//

Constant HRExecSize = 4; // Used with hrGetData to obtain the size of the Execute request vector.
// The vector consists of the CPU request as first element (when present)
// followed by Read and/or Write requests elements.

Constant HRExecReqType = 5; // Used with hrGetDataX to obtain the type of the Execute request element.
// Returns one of the following: ReadType, WriteType, SendType, or CpuType.

Constant HRnfsProc = 6; // Used with hrSetData and hrGetData to save and retrieve the process id
// of the local NFS process.

Constant HRioReq = 7; // Used with hrGetDataX to obtain the handle to an IO request structure
// (element of the Execute vector).

Constant HRResetReq = 8; // Used with hrSetDataX to set the specified element in the Execute request

```

```

// vector to null. This action is done when the original request element
// has been replaced by a more detailed operating system representation.

Constant HRlocalIO = 9; // Used with hrSetData to initiate a local IO request using the specified
// IO request handle.

Constant HRpostExecute = 10; // Used with hrSetData to post a completion event to the original Execute
// synchronization control logic. (All parts of an Execute statement must
// be completed before a process exits the Execute statement.)

Constant HRkbytes = 11; // Used with hrGetDataX to obtain the total data bytes (in Kbytes) for the
// specified IO request

Constant HRvolumeHandle = 12; // Used with hrGetDataX to obtain the handle of the associated volume for
// LocVolType and RemVolType io requests.
// The handle is used by volGetStripeSize() and volGetStripedDiskNumber()
// volume manager utility functions.

Constant HRkbytesOffset = 13; // Used with hrGetDataX to obtain the kbyte offset of the first IO record
// in the specified File based on the value of the FirstIo parameter on an
// execute Read or Write request. If FirstIo is not specified a random
// record number between 0 and max-1 is used as the first IO record.
// The offset is used by the volume manager to determine the disk on which
// the first IO record resides.

Constant HReqType = 14; // Used with hrGetDataX for Read and Write execute elements.
// Returns one of LocDiskType, RemDiskType, LocVolType, RemVolType.

Constant HRioReqCopy = 15; // Used with hrGetDataX to make a copy of the specified IO request

Constant HRioReqDisk = 16; // Used with hrSetDataX to set the disk number for the specified IO request

Constant HRioReqKbytes = 17; // Used with hrSetDataX to set the amount of data to be transferred

Constant HRioReqNumber = 18; // Used with hrSetDataX to set the starting record for the specified IO request

//-----
// Hardware request element type.
// Returned by HReqType when used with hrGetDataX.

```
3207 // Operating system interface constants (must match Strategizer internals)
// *** WARNING: changes in this section will cause execution time failure
// -----
```

```
// The Strategizer Operating System Model has been modified for release 2.2
// to take advantage of the new ADN object-oriented extensions.
// Strategizer users can extend this SES supplied capability by using the
// new user_extensions.adn option.
// -----
```

// INTRODUCTION

```
// The operating system exists as an instance of the class ses_OperatingSystem
// and a layer of software logic implemented in its behavior methods and
// associated server processes. This layer of logic lies between software
// processes running in application problem state and the underlying hardware.
```

```
// An association is made between an operating system name (the first column in the
// CSE.ops file) and an ADN OS behavior name (the sixth column of the CSE.ops file).
// Note that the operating system names are selected from a list (based on the
// CSE.ops file) via the GUI for each computer in a Strategizer model.
```

```

// Instances of an operating system are created for each computer that runs an
// operating system with an associated ADN OS behavior name by invoking that
// behavior to instantiate an OperatingSystem object and call its
// initializeSvc behavior.
// The default for this release is to define the ADN behavior "ADNNosSvc" for
// all the named operating systems. The operating system name is passed as a
// parameter to the operating system instance constructor.

// A knowledgeable Strategizer user can create a new operating system class by
// extending the OperatingSystem class supplied by SES in this file (System.adn).
// Such user extensions must be placed in the specially named user_extensions.adn
// file for proper processing.

```

// ADN PROCESSES AND STATE

```

// Software processes can execute in problem state and additionally in supervisor
// state (a new feature since release 2.0).

```

- // Processes that startup in problem state switch to supervisor state at specific points
 // (OS hook locations) to execute an operating system service and then return to problem
 // state.

```

// Processes that startup in supervisor state (the OS server processes) remain in
// supervisor state.

```

//-----

```

// OS behavior hooks are implemented as methods of an instance of the ses_OperatingSystem class
// or a user extension thereof specified in the user_extensions.adn file.
// The logic located at each hook is described along side the corresponding hook constant.
// Note: The hook constant is required on the return from each method as part of the hook
// protocol mechanism.

```

```

Constant INITIALIZESvc = 0; //The initializeSvc behavior is executed once for each associated
                           // computer by a special initialization process after a new instance
                           // of the ses_OperatingSystem class is created. These actions are taken
                           // by the ADN OS behavior (named in col. 6 of the CSE.ops file).
                           // The purpose of this logic is to create the associated server

```

```

// processes that make up part of the operating system.
// The operating system state data is maintained in the OperatingSystem
// instance field variables.
// The initializeSvc behavior of the ses_OperatingSystem class should
// be called as the first statement in any initializeSvc overriding
// behavior specified by the user to assure that the basic operating
// system services are properly initialized.
// Refer to the initializeSvc behavior logic for additional details.

// In the following hooks the active process switches from problem to supervisor state and executes the
// corresponding operating system service behavior. The hook constant value is passed back as the only
// return parameter. When the service is completed, the active process returns to problem state.

Constant EXECUTESvc = 1; // The executeSvc behavior receives control when the Execute statement is ready
// to be sent to the hardware.
// Individual elements in the request vector (prepared from the Execute
// statement) are checked for remote disk IO and IO operations involving
// files located on volumes. Substitution or modification of the original
// requests are made as appropriate. The requests are then passed on to
// the hardware model.
// Refer to the executeSvc behavior logic for additionl details.
// Note: It is strongly recommended that this behavior not be overridden
// by the user unless all the original logic is also included.

// The following set of four hooks are designed to work together to provide support for the implementation
// of communication protocol logic. This is expected to be the main part of the operating system logic that
// most users may be interested in extending.
// The service behaviors provided with release 2.2 contain no logic other than to surface addressability
// to the ses_Message object instance associated with the operation. The declaration for the ses_Message class
// is located in the Utilities.adn file.

// The following notes may help in use of the communication service hooks:
// - Synchronous messages execute the following sequence: sendSvc, receiveSvc, replySvc, and sendWaitsvc.
// - Asynchronous messages execute the following sequence: sendSvc then receiveSvc.
// - The sendSvc and replySvc are invoked just before passing control to the hardware.
// - The receiveSvc and sendWaitSvc are invoked just after returning from the hardware.

Constant SENDsvc = 2; // The sendSvc behavior is executed at the end of the software part
// of Send statement processing, just before the request is sent to the
// hardware. Upon exit from this section, the resulting request is sent

```

```

// to the hardware.

Constant SENDWAITsvc = 3;
// The sendWaitSvc behavior is executed early in the processing of an incomming
// message sent by the Reply clause of a Receive statement.
// Upon exit from this section, control is passed to the Wait clause of the
// original Send statement for processing of the message data fields.

Constant RECEIVESvc = 4; // The receiveSvc behavior is executed early in the processing of an incomming
// message from a Send statement.
// Upon exit from this section, control is passed to the Receive statement
// for processing of the message data fields.

Constant REPLYsvc = 5; // The replySvc behavior is executed at the end of the software part
// of the Reply clause (part of the Receive statement), just before the
// request is sent to the hardware.

Constant TASKSTARTsvc = 6; // Updates active task count stats
// Increments active task count
// Issues warning first time maximum count is issued

Constant TASKENDsvc = 7; // Updates active task count stats
// Decrements active task count

// -----
// The "hr" (hardware request data) utility functions are used to access specific data necessary
// to support the current operating system functionality. In release 2.0 this is limited to requests
// generated by the Execute statement.
// The constants defined below are used in combination with the following data access utility
// functions hrGetData/hrSetData to access scalar values, and hrGetDataX/hrSetDataX to access
// vector (or subscripted) values.

// CAUTION: In considering user defined extensions to the operating system the prospective user
// should become familiar with the data currently accessible at the ADN level.
// ----

Constant HRExecSize = 4; // Used with hrGetData to obtain the size of the Execute request vector.
// The vector consists of the CPU request as first element (when present)
// followed by Read and/or Write requests elements.

Constant HRExecReqType = 5; // Used with hrGetDataX to obtain the type of the Execute request element.

```

```

// Returns one of the following: ReadType, WriteType, SendType, or CpuType.

Constant HRnfsProc      = 6;   // Used with hrSetData and hrGetData to save and retrieve the process id
                                // of the local NFS process.

Constant HRioReq          = 7;   // Used with hrGetDataX to obtain the handle to an IO request structure
                                // (element of the Execute vector).

Constant HResetReq        = 8;   // Used with hrSetDataX to set the specified element in the Execute request
                                // vector to null. This action is done when the original request element
                                // has been replaced by a more detailed operating system representation.

Constant HRlocalIO         = 9;   // Used with hrSetData to initiate a local IO request using the specified
                                // IO request handle.
